

Computer science differs from other scientific disciplines in that it focuses not on solving or making discoveries, but on questioning our current understanding. The fact that one has successfully come up with an idea for a certain problem immediately raises the question of optimality. At the most basic level, we would like to answer what is the 'best' program that exists for a particular problem. To do this, we must understand a notation that allows us to determine if an algorithm is indeed solving the task, quantify its performance, and compare it to other algorithms. In this chapter, we introduce this basic notation. The chapter is divided into two main parts: the first is about induction, a mathematical technique for proving claims, and the second presents asymptotic notation, which we use to describe the behavior of algorithms over large inputs.

Chapter 1

Induction and Asymptotic Notations.

1.1 Induction.

What is induction?

1. A mathematical proof technique. It is essentially used to prove that a property $P(n)$ holds for every natural number n .
2. The method of induction requires two cases to be proved:
 - (a) The first case, called the base case, proves that the property holds for the first element.
 - (b) The second case, called the induction step, proves that if the property holds for one natural number, then it holds for the next natural number.
3. The domino metaphor.

The two types of induction, their steps, and why it makes sense (Strong vs Weak) - Emphasize the change in the induction step.

Example 1.1.1 (Weak induction). *Prove that $\forall n \in \mathbb{N} \sum_{i=0}^n i = \frac{n(n+1)}{2}$.*

Proof. Base: For $n = 1$, $\sum_{i=0}^1 1 = 1 = \frac{(1+1) \cdot 1}{2}$.

Assumption: Assume that the claim holds for n . Step:

$$\sum_{i=0}^{n+1} i = \left(\sum_{i=0}^n i \right) + n+1 = \frac{n(n+1)}{2} + n+1 = \frac{n(n+1) + 2 \cdot (n+1)}{2} = \frac{(n+1)(n+2)}{2}$$

□

Example 1.1.2 (Weak induction.). *Let $q \in \mathbb{R}/\{1\}$, consider the geometric series $1, q, q^2, q^3, \dots, q^k$. Prove that the sum of the first k elements is*

$$1 + q + q^2 + \dots + q^{k-1} + q^k = \frac{q^{k+1} - 1}{q - 1}$$

Proof. Base: For $n = 1$, we get $\frac{q^{k+1}-1}{q-1} = \frac{q-1}{q-1} = 1$. Assumption: Assume that the claim holds for k . then: Step:

$$1 + q + q^2 + \dots + q^{k-1} + q^k + q^{k+1} = \frac{q^k - 1}{q - 1} + q^{k+1} = \frac{q^{k+1} - 1 + q^{k+1}(q - 1)}{q - 1} = \frac{q^{k+1} - 1 + q^{k+2} - q^{k+1}}{q - 1} = \frac{q^{k+2} - 1}{q - 1}$$

□

Example 1.1.3 (Strong induction). *Let there be a chocolate bar that consists of n square chocolate blocks. Then it takes exactly $n - 1$ snaps to separate it into the n squares no matter how we split it.*

Proof. By strong induction. Base: For $n = 1$, it is clear that we need 0 snaps. Assumption: Assume that for **every** $m < n$, this claim holds.

Step: We have in our hand the given chocolate bar with n square chocolate blocks. Then we may snap it anywhere we like, to get two new chocolate bars: one with some $k \in [n]$ chocolate blocks and one with $n - k$ chocolate blocks. From the induction assumption, we know that it takes $k - 1$ snaps to separate the first bar, and $n - k - 1$ snaps for the second one. And to sum them up, we got exactly

$$(k - 1) + (n - k - 1) + 1 = n - 1$$

snaps.

□

1.2 Asymptotic Notations.

Definition 1.2.1. Let $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$. We say that $f(n) = O(g(n))$ if $\exists N \in \mathbb{N}, \exists c > 0$ s.t. $\forall n \geq N : f(n) \leq c \cdot g(n)$

Example 1.2.1. For example, if $f(n) = n + 10$ and $g(n) = n^2$, then $f(n) = O(g(n))$ (Draw the graphs) for $n \geq 5$: $f(n) = n + 10 \leq n + 2n = 3n \leq n \cdot n = n^2$

Definition 1.2.2. Let $f, g : \mathbb{N} \rightarrow \mathbb{R}$. We say that $f(n) = \Omega(g(n))$ if $g(n) = O(f(n))$, equivalently, $\exists N \in \mathbb{N}, \exists c > 0$ s.t. $\forall n \geq N c_0 g(n) \leq f(n)$

Example 1.2.2. Also if $f(n) = 5n$ and $g(n) = n^2$, then $f(n) = O(g(n))$ (Now discuss intuition - no matter how much we “stretch” f, g is still the winner)

Definition 1.2.3. Let $f, g : \mathbb{N} \rightarrow \mathbb{R}$. We say that $f(n) = \Omega(g(n))$ if: $\exists N \in \mathbb{N}, \exists c > 0$ s.t. $\forall n \geq N f(n) \geq c \cdot g(n)$.

Example 1.2.3. For example, if $f(n) = n + 10$ and $g(n) = n^2$, then $g(n) = \Omega(f(n))$

Definition 1.2.4. Let $f, g : \mathbb{N} \rightarrow \mathbb{R}$. We say that $f(n) = \Theta(g(n))$ if: $f(n) = O(g(n))$ and $f(n) = \Omega(g(n))$. That is, we say that $f(n) = \Theta(g(n))$ if: $\exists N \in \mathbb{N}, \exists c_1, c_2 > 0$ s.t. $\forall n \geq N c_1 \cdot g(n) \leq f(n) \leq c_2 \cdot g(n)$

Example 1.2.4. For every $f : \mathbb{N} \rightarrow \mathbb{R}$, $f(n) = \Theta(f(n))$

Example 1.2.5. If $p(n) = n^5$ and $q(n) = 0.5n^5 + n$, then $p(n) = \Theta(q(n))$

But why is this example true? This next Lemma helps for intuition:

Lemma 1.2.1. $\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} < \infty \Rightarrow f(n) = O(g(n))$

Proof. Assume that $l = \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} < \infty$. Then for some $N \in \mathbb{N}$ we have that for all $n \geq N$: $\frac{f(n)}{g(n)} < l + 1 \Rightarrow f(n) < (l + 1)g(n)$ Which is exactly what we wanted. \square

1.3 Examples with proofs.

Claim 1.3.1. $n = O(2^n)$

(This must seem very silly, but even though we have a strong feeling it's true, we still need to learn how to PROVE it)

Proof. We will prove by induction that $\forall n \geq 1, 2^n \geq n$, and that will suffice. Basis: $n = 1$, so it is clear that: $n = 1 < 2 = 2^n$ Assumption: Assume that $n < 2^n$ for some n . Step: We will prove for $n + 1$. It holds that:

$$n + 1 < 2^n + 1 < 2^n + 2^n = 2^{n+1}$$

\square

Claim 1.3.2. Let $p(n)$ be a polynomial of degree d and let $q(n)$ be a polynomial of degree k . Then:

1. $d \leq k \Rightarrow p(n) = O(q(n))$ (set upper bound over the quotient)
2. $d \geq k \Rightarrow p(n) = \Omega(q(n))$ (an exercise)
3. $d = k \Rightarrow p(n) = \Theta(q(n))$ (an exercise)

Proof. Proof (Of 1) First, let's write down $p(n), g(n)$ explicitly:

$$p(n) = \sum_{i=0}^d \alpha_i n^i, \quad g(n) = \sum_{j=0}^k \beta_j n^j$$

Now let's manipulate their quotient:

$$\begin{aligned} \frac{p(n)}{q(n)} &= \frac{\sum_{i=0}^d \alpha_i n^i}{\sum_{j=0}^k \beta_j n^j} = \frac{\sum_{i=0}^d \alpha_i n^i}{\sum_{j=0}^k \beta_j n^j} \cdot \frac{n^{k-1}}{n^{k-1}} = \frac{\sum_{i=0}^d \alpha_i n^{i-k+1}}{\sum_{j=0}^k \beta_j n^{j-k+1}} \leq \\ &\leq \frac{\sum_{i=0}^d \alpha_i}{\beta_k} < \infty \end{aligned}$$

And now we can use the lemma that we have proved earlier. \square

1.4 Logarithmic Rules.

Just a quick reminder of logarithmic rules:

1. $\log_a x \cdot y = \log_a x + \log_a y$
2. $\log_a \frac{x}{y} = \log_a x - \log_a y$
3. $\log_a x^m = m \cdot \log_a x$
4. Change of basis: $\frac{\log_a x}{\log_a y} = \log_y x$

And so we get that:

Remark 1.4.1. For every $x, a, b \in \mathbb{R}$, we have that $\log_a x = \Theta(\log_b x)$

Example 1.4.1. Let $f(n)$ be defined as:

$$f(n) = \begin{cases} f\left(\lfloor \frac{n}{2} \rfloor\right) + 1 & \text{for } n > 1 \\ 5 & \text{else} \end{cases}$$

Let's find an asymptotic upper bound for $f(n)$. let's guess $f(n) = O(\log(n))$.

Proof. We'll prove by strong induction that : $f(n) < c \log(n) - 1$ for $c = 8$ And that will be enough (why? This implies $f(n) = O(\log(n))$). Base: $n = 2$. Clearly, $f(2) = 6 < 8$ Assumption: Assume that for every $m \leq n$, this claim holds. Step: Then we get:

$$\begin{aligned} f(n) &= f\left(\lfloor \frac{n}{2} \rfloor\right) + 1 \leq c \log\left(\lfloor \frac{n}{2} \rfloor\right) + 1 \\ &\leq c \log(n) - c \log(2) + 1 \leq c \log(n) \quad \text{for } c = 8 \end{aligned}$$

□
